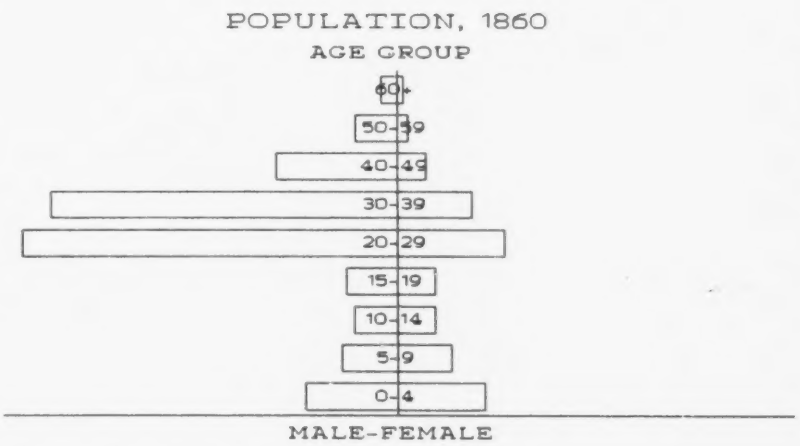
STATE PROJECTION BY AGE AND SEX 74

HISTORICAL STATE POPULATION. 75

HISTORICAL PERSPECTIVE

California's first European migrants came to San Diego in 1769. They built missions, pueblos and presidios along the coast. Few migrants came to the area over the following 75 years and by 1848 the population excluding Indians, was estimated to be 14,000--about the size today of the city of Sanger in Fresno County. But with the discovery of gold in 1848, people poured into the Sierra Nevada and the San Francisco Bay Area. In 1850 the mining areas had 60-70 percent of the State's population, which was about the current size of Salinas in Monterey County. There were 12 men for every woman and 75 percent of these men were between the ages of 20 and 40 years old. This was California's most unique demographic period.



In 1860 the population of the State was 380,000, about the same size as Long Beach today. During this time, the population in the mining areas began to either stabilize or decline, while the Bay Area

continued to grow rapidly. But by 1900, San Francisco's growth began to slow while the population in Los Angeles soared. In 1910 there were only one and a quarter men for every woman, compared to the twelve to one ratio in 1850. Throughout this 50-year period, the 35-39 age group was the largest. By 1920, the State had reached a population of 3.4 million, approximately the size of the city of Los Angeles today.

The 1930s brought the depression. The State's population grew only about 20 percent compared to 70 percent in the previous decade. During this period about 20 percent of the migrants into California came from Oklahoma and Texas and these migrants tended to go to the central valley rather than the metropolitan areas. The crude birth rate--the total number of births divided by the total population--was 13 per 1000 and the median age was 31.4 years.

World War II ended the heavy migration to California's central valley. Between 1940 and 1950 the population increased by 50 percent, with four-fifths of this gain in metropolitan areas. For the first time since 1860, San Francisco grew faster than Los Angeles because of the ship building industry. San Diego was also affected by war-time activities realizing a 90 percent population increase. The crude birth rate had increased 80 percent and was 24 per 1000 by 1949 and the median age had risen slightly to 32.1 years in 1950.

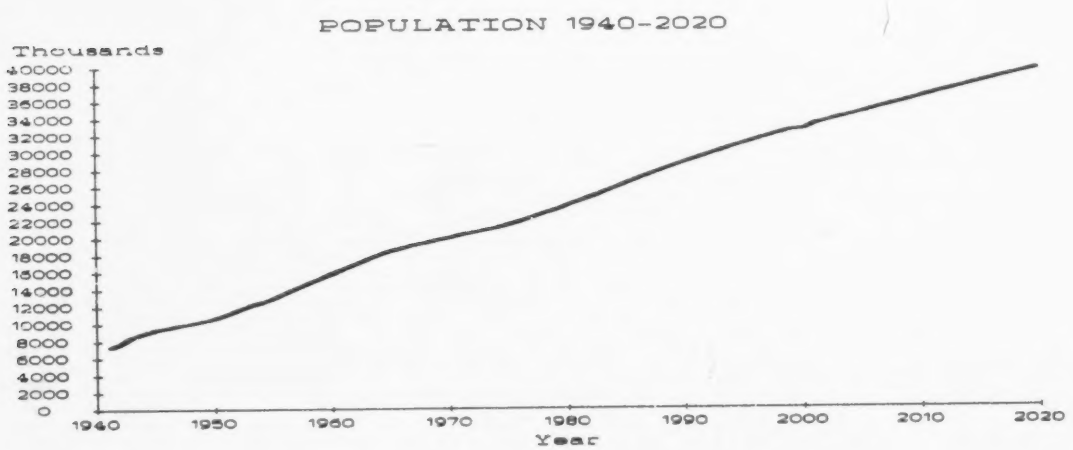
Between 1950 and 1960 growth occurred in areas where defense oriented industries were located. Santa Clara County more than doubled and the building of Vandenberg Air Force Base spurred growth in Santa Barbara. The crude birth rate peaked in 1957 at 25 per 1000. It was during the 1960s that Orange County's population swelled, growing 102 percent. During this period San Francisco lost population and the crude birth rate reversed its trend and dropped to 18 per 1000 in 1968. Following the baby boom, the State's median age dropped to 28.1 years in 1970.

During the 1970s population growth in California declined to an annual average of 1.9 percent. Slowdowns in the defense-related industries during the early part of the decade led to some net domestic out-migration. San Francisco continued to lose population during this time, while growth accelerated in the Sierra Nevada foothill counties. The crude birth rate in California bottomed out in 1974 at 14. The median age had reached 30 years by 1980.

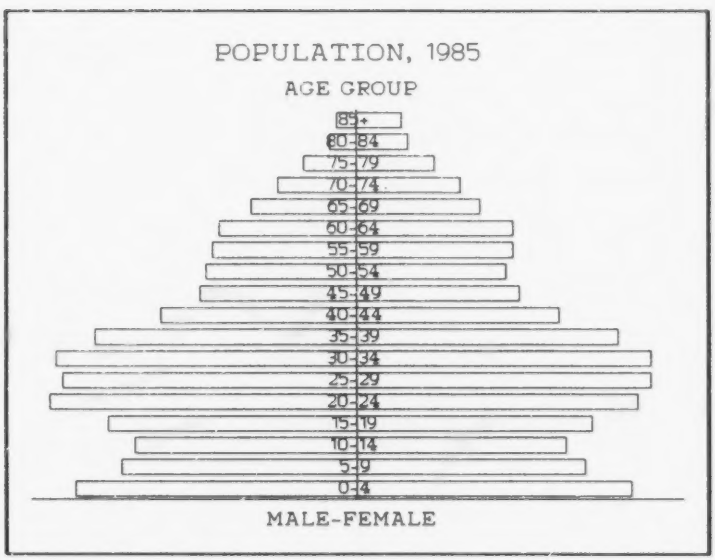
IMPLICATIONS OF THE PROJECTIONS

If trends of the past 15 years continue for the next 35 years, California's population will top 39 million in the year 2020. The State as a whole will gain over 13 million people. About half of the increase will be due to natural increase, i.e., births minus deaths, and half to net migration. Over the long run, both components of population change will slow as the State ages.

Los Angeles, San Diego, and Orange counties will retain their one, two, and three rankings in population size throughout the projections period. San Bernardino and Riverside counties, however, will surpass Santa Clara to become the



fourth and fifth most populous in the State. By the year 2020 nine counties in California will have more than one million residents each. The central valley, foothill, and south coast counties will increase their proportion of the State's population while the Bay Area and Southern California will represent a smaller percentage. However, the Bay Area and Southern California counties will still represent almost three-quarters of California's total population. Southern California will experience the largest absolute increase, over 7 million people; but at the same time, the Sierra Nevada foothill counties will record a 120 percent gain. Over the entire 35-year period, Lake County will register the highest percent increase and Los Angeles, the greatest absolute growth. San Francisco will be the only area to decline over the projection period.



The median age in the State will rise from 31.3 in 1985 to 35.4 in the year 2000 to and 36.7 in 2020. This increase represents the aging of the baby boom cohort. In 1985, Lake County had the highest median age and Kings County, the lowest. By early in the next decade, San Francisco will be home to the oldest and Merced to the youngest populations. In 2020 Merced will still have the lowest median age but Alpine will have the highest.

The percent of children in the child care ages (0 to 4 years old) will decline as a proportion of the population between 1985 and

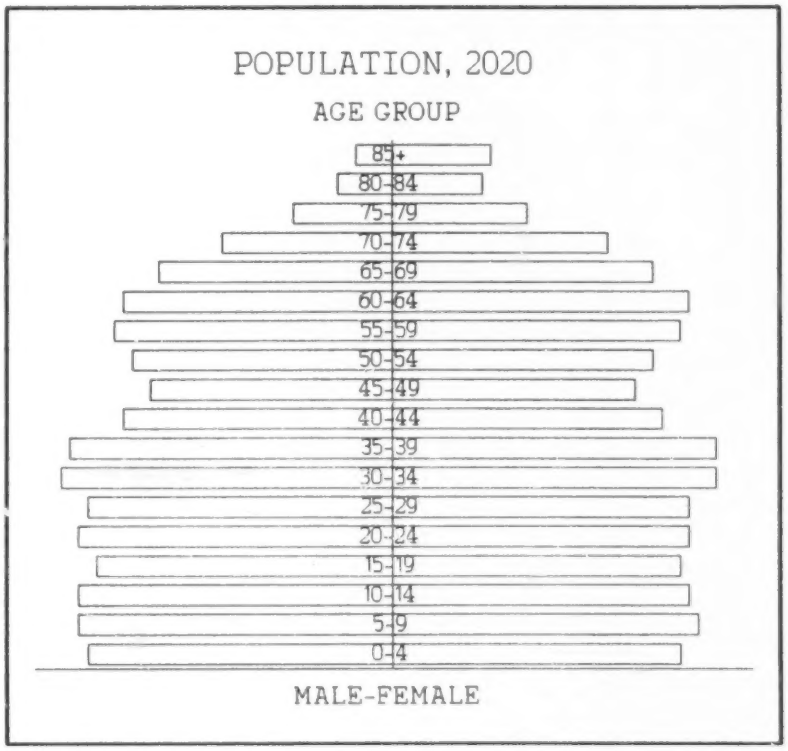
2020 although their actual numbers will grow by about 375,000. Marin and Alpine Counties had the lowest concentrations of these age groups in 1985 and Merced the highest; Alpine and Merced will maintain their rankings in 2020. Children 5 to 13 years old, the primary school ages, registered about 12 percent of the population in 1985 and will remain constant in 2020. Their proportion jumps slightly toward the end of this century, however, as today's births reach this age group. Again, Merced has the greatest percent of people in this age group throughout the projection period; and while San Francisco had the smallest percent in 1985, Alpine takes over that distinction after 2000. Children in secondary school ages follow a pattern similar to those in primary school ages (the proportion rises slightly in the year 2000 and then drops back to the 1985 level in 2020).

The concentration of people in the 18 to 24 age group--the group that traditionally goes to college, forms new households and enters the labor force--will decline throughout the projection period. In absolute terms, however, they will by grow about a half a million. Yolo County will have the largest percent of this age group due to the student population at the University of California, Davis. Although Lake County has the smallest percent today, Marin will have the least in the future.

The proportion of population in the labor force age group of 25 to 64 years will remain fairly stable at around 51 percent throughout the forecast period. The proportions vary by county from a low in the year 2020 of 43 percent in Mono to a high of 57 percent in Monterey due to the influence of the military.

It is forecast that the older age groups will be the fastest growing due to the aging of the baby boomers and increased life expectancy. Those 65 years and over will climb from 11 percent of the population in 1985 to nearly 16 percent in 2020, and at the same time, those 85 years and older will increase by 135 percent. These changes in the age structure result in the dependency ratio (the younger and older populations divided by the working age population) rising from 52 per 100 in 1985 to 59 per 100 in 2020. This increase in the ratio reflects the aging population.

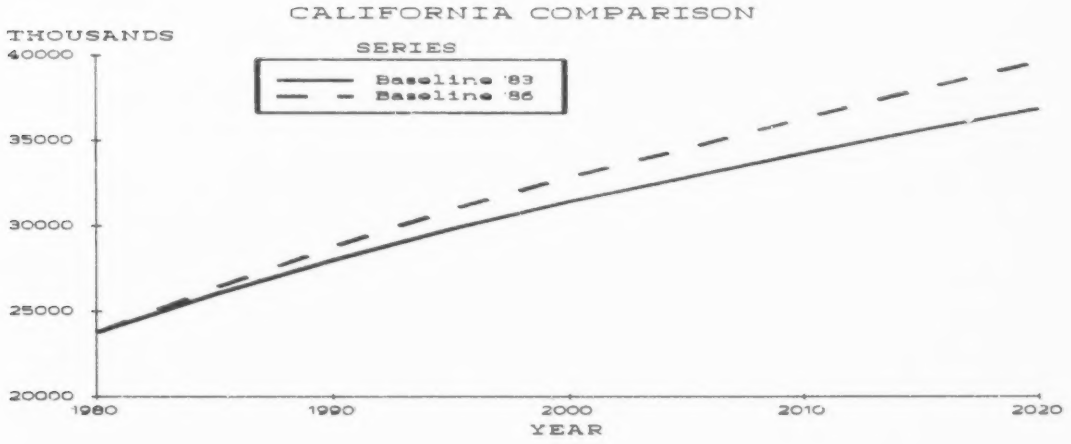
Other interesting ramifications of the population projections include changes over time in crude birth rates, age of mothers at birth and life expectancy. As the baby boom women move out of childbearing ages, the crude birth rate drops from its current level of 17.4 to 13.3 in 2000. The rate then levels off at 13.1 in the year 2020. The median age of mothers at birth rises slightly from 26.05 in 1985 to 26.20 in 2020. Life expectancy increases from 74.5 in 1985 to 75.5 in 2000 and is then level to 2020. To detail this further, female life expectancy rises from 77.4 in 1985 to 78.0 in 2020. At the same time, male life expectancy increases from 71.6in 1985 to 72.7 in 2020. The changing age structure results in a population pyramid that doesn't reflect the typical triangle shape.



It is interesting to note how these population projections differ from those released in 1983. By the year 2020, these latest projections are about 7.5 percent

higher than the previous series. This increase results not only from the change in methodology to include undocumented migrants, but faster than anticipated growth between 1980 and 1985. Generally, these new projections are somewhat higher in the younger age groups and somewhat lower in the older age groups. On a county-by-county comparison, the most substantial downward revision was in Mono County. It was revised down almost 40 percent in 2000 and about 55 percent in 2020. The largest upward revisions were in San Benito and Merced counties. San Benito was revised up 21 percent in 2000 and Merced was increased 39 percent in 2020. These changes are mostly due to revised levels of migration in the first half of the decade which had not been anticipated.

As these trends show, the characteristics and behavior of the population in California will change over time. Analyzing the demographic trends will enable better planning.



TECHNICAL NOTES

The Department of Finance uses a baseline cohort-component method to project population by age and sex. A baseline projection assumes current economic, political, and social status; people have the right to migrate where they choose; and no major natural catastrophes or war will befall the State or the nation. A cohort-component method traces people born in a given year through their lives. As each year passes, cohorts change due to the mortality and migration assumptions. New cohorts are formed by applying the fertility assumptions to the women of childbearing age.

Basic Civilian Population

The basic civilian population excludes special populations--military personnel and their dependents, college students, and the institutionalized. The active military, their spouses and children, are removed from the basic civilian population and held constant throughout the projection period. Persons in State mental hospitals, juvenile and adult correctional facilities, and colleges are removed from the site of the institution and allocated back to their county of origin. The benchmark is the 1980 Census. Data are obtained for each county by sex and single year of age. The census benchmark is then adjusted to reflect the special populations.

The military population is estimated by using annual reports from the military bases adjusted to reflect the 1980 decennial enumeration. The sex and age of the military are based on the distribution at the time of the census. Military dependents and their characteristics are estimated using the Public Use Microdata Sample from the 1980 Census. The ratio of dependents to active military is assumed to remain constant over time.

The definition of college students is limited to those students living away from home, 29 years old and younger, and enrolled full-time. Data are obtained from annual reports of fall enrollment provided by the University of California and the California State University and Colleges. Data for private colleges are obtained from administrative records prepared for the federal government.

The Departments of Corrections, California Youth Authority, Developmental Services, and Mental Health provide current and future data on their institutionalized populations. The administrative records are allocated by age and sex using the 1980 Census when these characteristics are not available from the departments' reports.

Survival, Fertility, and Migration Rates

Survival rates were developed using deaths by age for the decade of the 1970s from the Department of Health Services. Mortality rates were computed using the average of 1979 and 1980 deaths. This method compensated for any unusual occurrences that may have taken place in any one year such as a flu epidemic. The basic civilian population served as the base to compute the mortality rates which were then converted to survival rates. These rates were derived for single years of age by sex and represent one-year rates.

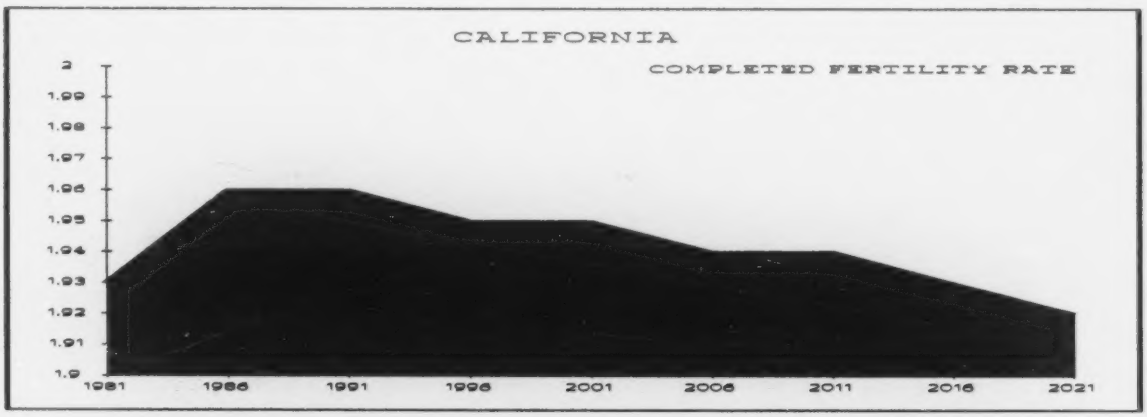
The age-specific fertility rates for 5-year cohorts were developed for the basic civilian female population aged 15 to 44 years. The average of births by age of mother for 1982, 1983, and 1984 were used. Births to women aged less than 15 and over 44 years were added to the youngest and oldest cohorts, respectively.

Three methods were used to compute the projected migration rates. First, the basic civilian population for 1970 was estimated, adjusted for undercount, and survived to 1980. Births were added to create new cohorts. The 1980 basic civilian population was further adjusted to remove Southeast Asian refugees whose immigration was administratively determined. The survived 1970 basic civilian population was compared to the 1980 basic civilian population and any differences were assumed to be migration. Since this was a residual category, the migration estimate also

included any errors resulting from the reporting of births, deaths and enumeration errors. The estimates of migration by age and sex were converted to annual migration rates and percent male. These rates were smoothed using the 5-year cohort rates. For the second method, migration rates were developed using the residence 5 years ago question from the 1980 census. These rates were for 5-year age groups. An administrative records method, which represented trends of the 1980s, was the base of the third set of migration rates. For the population under 15 years, school enrollment was the indicator; for the population 15 to 64 years, drivers license address changes were used; and for the over 65 years population, medicare enrollment was the indicator used. The three methods were averaged to reflect recent and long-term trends.

Assumptions

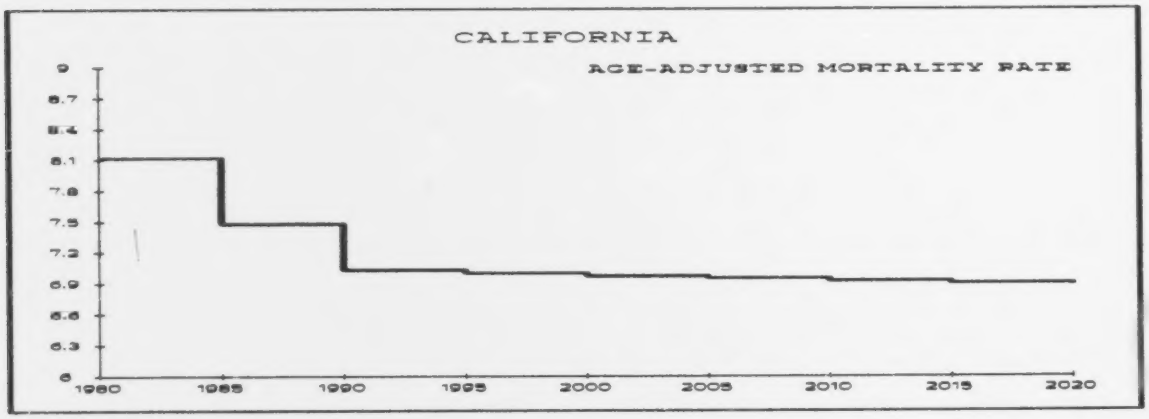
The total fertility rate represents the number of children a woman would have in her lifetime if she experienced the age-specific rates occurring in a particular year. Nationally, the total or completed fertility rate rose during the 1950s, peaked in the early 1960s, declined until 1975, and has leveled in recent years.



The Census Bureau projects fertility to continue moderate gains from the current level of 1.83 to 1.96 in 2010. Thereafter, the Bureau projects a downturn to 1.90 and then stability.

The Department of Finance fertility assumption is changed minimally from the Baseline '83 projection series. In that projection it was assumed county-specific fertility rates would merge toward the Census Bureau's national completed fertility assumptions. Because of California's unique race and ethnic structure, the merging process was one-half of the current difference from the national rates in 100 years. Recent analysis has shown that although the State and the nation are no longer merging--California's fertility rate is rising while the national rate is falling--most counties were closer to the national rate in 1984 than they were in 1980. Therefore, although we continued to merge the rates to the national assumptions, we have lengthened the period to 200 years.

In the past, mortality trends have graphed like a staircase. Rapid declines in mortality due to medical breakthroughs are followed by periods of only slight declines. From 1940 to 1960, mortality dropped only slightly, but earlier in the century

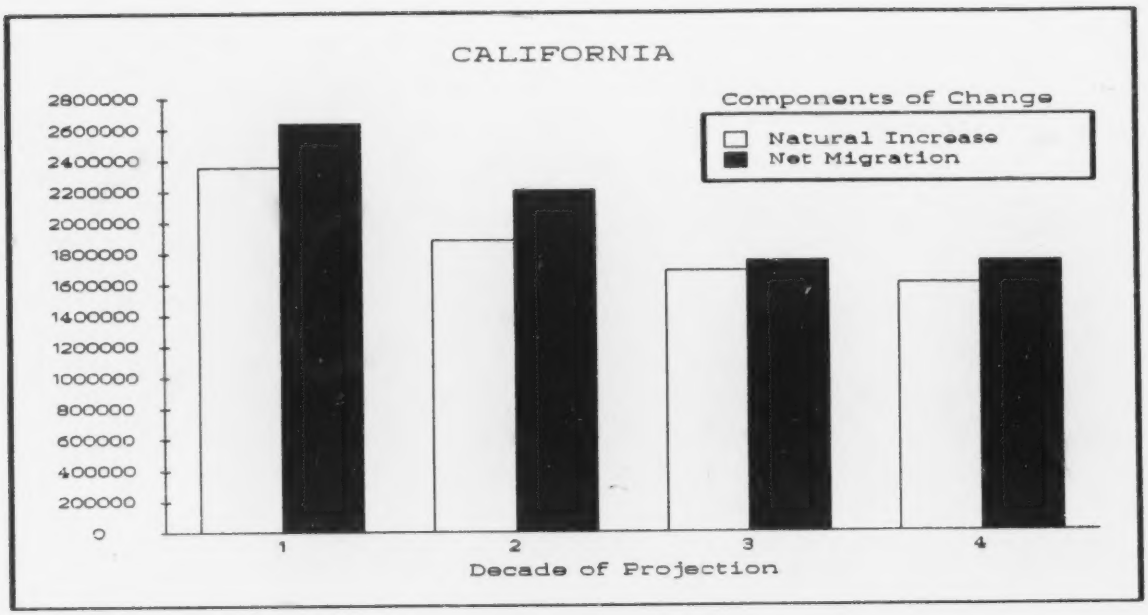


substantial increases in life expectancy resulted from the control of infectious diseases. The past couple of decades have again shown sharp declines in mortality. These improvements are apparently because of the early detection and treatment of cardiovascular disease and changes in life style which have reduced heart attack and stroke deaths. The most recent federal projections assume an increase in life expectancy from 74.8 years in 1982 to 79.6 years in 2050. (It should be noted that it is assumed life expectancy will increase only half as rapidly after 2005 as it did before.)

The Department of Finance handles mortality rates in a manner similar to the merging of the age-specific fertility rates. County-specific age and sex mortality rates will be merged to one-half their current difference from the national rates in 200 years. Again, California's atypical age and race make-up mandate a longer period to merge to national assumptions.

Migration is the most volatile of the components of population change. When describing the characteristics of migrants to California it is useful to classify them as domestic and foreign. Domestic migration peaked in the 1950s, bottomed out in the early 1970s and has been on the increase since that time. The number of foreign migrants to the State has been climbing for the past 15 years but may have recently crested. California's net migration had consisted of about 30 percent domestic and 70 percent foreign in the first half of this decade but current indicators show a trend toward a 50-50 split.

Because our projection is a baseline, we assume net migration will follow past trends. Our method is to weight the most recent 2-year period and modify this course into the future to reflect long-term trends. Using analysis of historical data, a weighted average, the most recent data available, and our best judgment we project California's net migration at an annual average of 215,000 out to the year 2020. This is an increase of almost 30 percent from the migration assumption in the Baseline '83 projections. It is assumed that domestic net migration will gain somewhat despite less secondary migration of Southeast Asian refugees. This slowdown will be more than offset by a backlog of migrants deferring moving during the recession of the early 1980s and the slowing outflow of Californians to oil dependent economies. Foreign net migration will



continue at the current level. Although the influx of refugees has slowed, as they and other immigrants receive citizenship, these new citizens will apply to bring additional family members to this country. These family members are not subject to the quota limitations.

County migration assumptions were made with input from local planners. Surveys were sent to all counties and regional councils of governments. Over 80 percent of the counties were represented by written responses to the survey. A follow-up telephone survey solicited response from an additional 10 counties and the remaining counties were contacted through the annual city/county visits program. Survey results were compared with internal analyses and adjustments were made where necessary.

Demographic Model

The basic civilian benchmark population is projected using the final assumptions--fertility and mortality will merge toward the national rates and there will be an annual average net in-migration to California of 215,000 for the next 35 years. New cohorts are created by applying the fertility assumptions to the women of childbearing ages. The population ages with time as age/sex-specific survival rates are applied to the population at risk. In addition, the overall migration assumption is distributed using the assumed age/sex migration rates. The process is carried forward for 40 years from 1980. For the years 1980 through 1985, the populations are benchmarked to the Department of Finance's current estimates series, 1985 E-2.

Projecting Special Populations

The special populations are projected, returned to the county of residence, attendance or institutionalization and added back to the basic civilian population. Age/sex composition of the special populations is estimated by applying rates developed from the 1980 data to the local population. Control totals are obtained from the administering State department. The military and their dependents are held constant after 1985.

The user is reminded that these numbers depict only one possible course of future population change, one attempting to reflect recent trends in fertility, mortality, and migration. These projections do not necessarily show what is most desirable, rather what can reasonably be expected if current trends continue for the next 35 years.
